

Conservation of Angular Momentum.

In translatory motion, the linear momentum of a single particle is expressed as $p = mv$. Now the question is that what is the analogue of linear momentum in rotational motion? In rotational motion, the analogue of linear momentum is angular momentum.

Consider the case of a particle A having linear momentum P .

The angular momentum L of the particle A with respect to fixed

point O as origin is defined as

$$L = r \times P \quad \text{--- (1)}$$

where r is the vector distance of the particle from origin O.

The angular momentum is a vector quantity. Its magnitude is given by

$$L = r p \sin \theta \quad \text{--- (2)}$$

where θ is the angle between r and p . The direction of L is perpendicular to the plane formed by r and p .

When a particle moves with angular velocity $\vec{\omega}$ in a circle, then its angular momentum is given by

$$\begin{aligned}L &= \vec{r} \times \vec{p} \\&= \vec{r} \times m\vec{v} \\&= m(\vec{r} \times \vec{v}) \\&= m[\vec{r} \times (\vec{\omega} \times \vec{r})]\end{aligned}$$

$$\text{or, } L = m r^2 \omega \quad \text{--- (3)}$$

Torque:- When a force acts on a particle A, then the moment of the force or torque about O is defined as

$$\vec{\tau} = \vec{r} \times \vec{F}$$

We know that

$$F = \frac{dp}{dt}$$

$$F = \frac{d}{dt}(mv)$$

$$\therefore \tau = \vec{r} \times \frac{d}{dt}(mv)$$

$$\tau = \frac{d}{dt}(m\vec{v} \times \vec{r})$$

$$\text{or, } \tau = \frac{dL}{dt}$$

This Torque = rate of change of angular momentum

When $\vec{\tau} = 0$, $\frac{dL}{dt} = 0$, or $L = \text{constant}$

So If the total torque on a particle is zero, the angular momentum of the particle is conserved. This is known as conservation of angular momentum.
